HAZARDOUS MATERIALS TRANSFER SYSTEM AND METHOD

Cross-Reference to Related Applications

[0001] This application is a continuation of U.S. Application No. 10/032,367, filed December 18, 2001, which claims the benefit of U.S. Provisional Application No. 60/256,718, filed December 19, 2000, both of which are hereby incorporated herein in their entireties by reference.

Field of the Invention

[0002] The invention relates generally to the transfer of hazardous materials, and more particularly to a method of transferring hazardous materials within an environmentally closed system for protecting the health and well being of personnel responsible for the materials transfer.

Background of the Invention

[0003] The transfer of hazardous materials is known to present potential problems to both the environment within which the hazardous materials are being used, and to the user responsible for handling the materials. There is a particular need to control such transfer of hazardous materials without an undue reliance on the skill or training of the personnel handling the materials. It would be preferable is such transfer could be an easy as filling ones gas tank at a self-service gas station, and in particular not require cumbersome and expensive protective wear. There is further a need handle such hazardous materials with a thought of protecting the environment.

Summary of the Invention

[0004] The present invention, herein described and embodied in a chemical materials transfer system and method, includes an automated system useful in

mosquito control, by way of example, for transferring hazardous chemicals from a chemical storage tank to a tank on board a vehicle or aircraft from which the chemicals will be distributed. The chemical materials transferred using the system and method of the present invention remain within a closed (gas sealed) environment in order to provide the maximum personal protection to the user during a transfer operation.

[0005] While not the same as filling ones automobile fuel tank with gasoline, operation of the system is intended to be as simple. However, embodiments of the present invention prevent the hazardous materials, both liquids and gases, from escaping into the environment. As a result, there is no need for personnel protective suits or re-breathing equipment, and the possible exposure to the chemical is still dramatically reduced. The present invention provides a capability to mix at varying ratios as well as safely transfer the hazardous material.

[0006] An automated system, as herein described by way of example, is useful for mosquito control personnel required to transfer and/or mix harsh chemical materials with a diluent from a chemical materials storage drum to a storage tank on board a vehicle or aircraft. The embodiment of the present invention herein described discloses a closed system for providing personal protection.

[0007] The present invention, a fluid materials transfer system useful for transferring hazardous fluids form a source to a target while maintaining the fluid materials within a closed environment in order to provide the maximum personal protection to the user during a transfer operation, comprises fluid storage means for storing a fluid within a closed environment, first flow control means operable with the fluid storage means for delivering a fluid from a source location thereto while maintaining the fluid within the closed environment, sensing means for sensing an amount of fluid carried by the storage means, second flow control means operable with the storage means for delivering the fluid therein to a target location while maintaining the fluid within the closed environment, and processing means operable with the first

2

and second flow control means for controlling flows therewith in response to an amount of fluid sensed by the sensing means.

[0008] A method aspect of the invention includes transferring hazardous fluids from a source to a target while maintaining the fluid materials within a closed environment in order to provide the maximum personal protection to the user during a transfer operation comprising storing a fluid within a closed environment, delivering the fluid from the source location while maintaining the fluid within the closed environment, sensing an amount of fluid from the storing, delivering a controlled amount of the fluid to a target location while maintaining the fluid within the closed environment, and controlling the delivering of the fluid from the source location to the target location in response to the sensing of the amount of fluid being stored.

Brief Description of the Drawings

[0009] Embodiments of the invention are described by way of example with reference to the accompanying drawings in which:

[0010] FIG. 1 is a block diagram illustrating an embodiment of the present invention including a closed system for the mixing and transfer of chemicals;

[0011] FIG. 2 is a block diagram of an embodiment of the present invention illustrating elements used for transfer of a hazardous chemical material from a source to a target tank;

[0012] FIGS. 3A, 3B, and 3C present a block diagram of an embodiment of the present invention illustrating elements used for mixing and transfer of multiple chemicals from source to target tanks; and

[0013] FIG. 4 is a block diagram illustrating one system controller operable with the embodiments of FIGS. 1-3.

Detailed Description of the Preferred Embodiments

[0014] The present invention will now be described more fully hereinafter with reference to the accompanying drawings, in which embodiments of the

3

present invention are shown by way of illustration and example. This invention may, however, be embodied in many forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art. Like numbers refer to like elements throughout.

[0015] With reference initially to FIG. 1, the system **10** illustrative of the present invention and herein described by way of example, includes a first subsystem **12** for illustrating a transfer of a highly hazardous material such as Dibrom (dibromochloropropane-a colorless, halogenated, carcinogenic hydrocarbon used as a pesticide, fumigant, and nematocide, and restricted in usage), a second subsystem **14** for illustrating a mixing and transferring of environmentally harmful materials, by way of example, and a controller **16** operable with both subsystems for controlling the transfer of the materials to be handled and keeping a record thereof. Expanded details of each will be addressed with reference to FIGS. 2-4. It is expected that the first subsystem (CS1) **12** will use Teflon fittings and other special processing components (pumps and valves) to handle the Dibrom product. The second subsystem (CS2) **14** will have additional components to provide for the mixing process with oil or water as may be required by the particular chemical material for the pre-selected use.

[0016] With continued reference to FIG. 1, consider the mechanical aspects of the present invention with reference to those needs known in the mosquito control industry. The embodiments illustrated with reference to the accompanying drawings accommodate the transfer of chemical materials from source tanks **18** such as 30, 55, or 275-gallon drums or bulk containers. Elements herein described for the embodiments illustrated, such as closed connectors may be selected from trusted and reliable manufacturers, and are herein presented are for illustrative purposes. Continuing with the example for mosquito control, a target tank **20** in the transfer may include a chemical container to be transported onboard a vehicle, such as a pickup truck, which

4

truck may be part of the system of the present invention. This target tank **20** will likely have a15-20 gallon capacity, be UV resistant, and preferably be manufactured from a high-density polyethylene. Typically, larger containers will the target tank **20** when used on an aircraft from which the chemical will be spread.

[0017] Some chemical materials (chemicals) planned for use may require mixing with a diluent, such as a light oil or water. Mixing ratios may typically range from 4:1 to approximately 15:1 and may be either mechanically adjusted or logic controlled. Generally, most chemicals used in mosquito control will not require mixing and are known generally known as ready-to-use (RTU) chemicals. As will be described in more detail later in this section, a connector **22** on a vehicle container will be sealed while connected or unconnected to any supply line **24**. The connector **26** on the supply line **24** is also sealed to prevent leaks while unconnected. As is described more fully with reference to FIGS. 2 and 3A, 3B, and 3C, the supply hose **28** connected to the vehicle is preferably not pressurized while not in use. Transfer times may range from approximately 5 gallons per minute for ground vehicles to about 20 gallons per minute for aircraft. Any system component contacting the chemical must be compatible with the harsh, corrosive mosquito control chemicals, such as Dibrom, by way of example. A Material Safety Data Sheet (MSDS) for Dibrom will be provided as well as material compatibility from AMVAC, the manufacturer of the chemical. Baytex and Fyfanon are other chemicals known to be corrosive and hazardous, thus requiring care when handling. The system **10** will automatically stop the transfer of the chemical materials when the target tank **20** is full. The system **10** as illustrated with reference again to FIG. 1, with further details illustrated in FIG. 4, includes a manually operated emergency stop button **30** which when activated will cause an override any automatically operated stop or start control. The emergency stop button **30** for the transfer process is mounted on a user interface panel of the controller **16**. The stop button removes the 24 volt system power **31** supplied, thus stopping all operations after emergency stop flow valves have been activated, which

5

valves are described later in further detail with reference to FIGS. 2 and 3A, 3B, and 3C. The system **10** will capture or re-circulate any vapor generated by the chemical materials during transfer. Also, an alarm **48** is activated which is separately battery powered.

[0018] With reference again to FIG. 1 and specifically the controller **16**, consider the intelligence and control aspects of the present invention. The system **10** controls flow of the chemical materials and meters its presence within a closed loop. The controller **16** controls and records the operation and data collection for both the first subsystem (CS1) **12** and the second subsystem (CS2) **14**. Individually controlled operation is preferred, but the system **10** and its controller **16** may not be limited to an individual or a simultaneous control of both subsystems, which control will depend on the operation and the support personal. Therefore, one subsystem, dual subsystems, two distinct subsystems, or any combination will be selected by a used to meet the need.

[0019] By way of example, the metering method as herein described includes use of weighing devices such as load cells **33**, as will be further described and illustrated with reference to FIGS. 2 and 3A, 3B, and 3C, but it is expected that other methods and devices, such as in-line metering will be used by those of skill in the art now having the benefit of the teachings of the present invention. Flow data is stored in a computer memory, and data reporting may include but is not limited to total chemical material per vehicle, date and time chemical material was transferred, person performing the transfer, vehicle number, type of chemical material transferred, total amount of chemical material used per day, and the cumulative total. A graphic display **34** is provided. Password entry or card reader **36** data entry will be required for access to the controls. In addition, a keypad **38** is provided for data entry for the embodiment herein described. Desired amounts of material to be transferred will be programmed, and an automatic shut-off provided as an override. The graphic (LCD) display **34** and the keypad **38** to enable user commands to the system **10** and the ability to view data relating to the transfer process. Reports on the transfer

6

process are available via an RS232 connection port either in real-time or as a call up report.

[0020] As above described, the present invention provides for chemical materials transfer while providing personnel and environmental protection. As herein presented, by way of example, for the hazardous material Dibrom, and for certain other mosquito insecticide materials, the standalone first subsystem (CS1) **12** may be required, and will need to be dedicated to that specific chemical material or product throughout its use, or until thoroughly cleaned. With such a requirement, a separate standalone subsystem, such as the second subsystem (CS2) **14** will be used to transfer, or mix and transfer, all other chemical materials for the mosquito insecticides anticipated for the example herein described. Again, it is anticipated that various alternatives, combinations and sub-combinations of the embodiments herein presented by way of example, will be developed now having the benefit of the teachings of the present invention.

[0021] With reference again to FIG. 1, the source tanks **18** carrying a supply of insecticide carry a bar code ID strip **40**. The bar code strip **40** is read by a bar code reader **42**, which also transmits the data to the controller **16** via an RF signaling unit **44**. This will permit identifying that the source (supply) tank **18** is carrying an acceptable product. The controller algorithm will utilize known bar code data provided by a supplier, a customer identification number, and chemical utilization data for the particular source tank to qualify that source tank as being acceptable for use. Provisions for the bar code reader **42** are included in the controller **16**. As a further safety consideration, a shower and eye wash station **46** is provided as a part of the system **10**. An RS232 connection **48** is also used as will be described later in further detail.

[0022] The controller **16** includes numerous inputs and outputs (I/O) to each subsystem **12**, **14** for an operator interface, the bar code reader **42** and the RS-232 serial port **49**. By way of example, the second subsystem **14** illustrated with reference to FIGS. 3A, 3B, and 3C, will have I/O which will include: six 4-20 mA inputs from the load cell summations, differential

7

pressure sensor, and the pressure transducer to the A/D on the system; two pulse width modulated (PWM) signals at 24 volts from the system **14** to pumps P2 and P4 pumps; and two logic 5 volt signals to the controller **16**; and ten 24 volt control commands from the controller **16** to the subsystem **14**.

[0023] The first subsystem **12** will have direct I/O which include: two 4-20 mA inputs from the load cell summations, pressure transducer to an A/D converter for the controller **16**; one 24 volt PWM signal to a pump (P2); three logic 5 volt signals to the controller **16**; and six 24 volt control signal commands from the controller **16** to the first subsystem (CS1) **12**.

[0024] With reference again to FIG. 4, and by way of example, a processor **17**, including a TDS2020 and a Mother Board with I2C paths can satisfy these I/O requirements. Therefore, while one may prefer using a dual TDS2020 implementation based on desired control, one is probably not required.

[0025] Consider the operation of the first subsystem **12** with reference again to FIG. 2. The chemical material being used is Dibrom, a corrosive insecticide in a liquid form carried in the source tank **18**. A dry connector (manufactured by Micro-Matic) is used for the connection **22/26,** as earlier described with reference to FIG. 1, to this mosquito control chemical source. The chemical material transfer flow process is automatic and is controlled by the controller **16**, after the desired start data have been entered through the keypad **38**, by way of example. Transfer process feedback is achieved by reading data from the sensors and process hardware control is via on/off switches at 5 volts, 24volts or PWM signals to pumps, as illustrated with reference to FIG. 4.

[0026] The measurement accuracy of the total chemical transferred will depend upon the accuracy of the load cells **33** on the first and second tanks **50, 52** (also identified in FIG. 2 as t1 and t2). The error in measurement will be less than 2%. The transfer of chemical materials using the first subsystem **12** will assume that the requirement includes transferring the Dibrom from the source tank **18** to the target tank **20** without a need for mixing, unlike the example described with reference to FIG. 4 illustrating the second subsystem **14**. The sequential process steps for the insecticide chemical transfer from

the source tank **18** to the target tank **20** located on an aircraft will be as follows:

[0027] The controller **16** described earlier with reference to FIGS. 1 and 4, verifies at an initial time (time #0) that the first tank (t1) **50** and the second tank (t2) **52** are at a "full" level. If the first tank **50** is not full, a first pump (p1) **54** is switched on. If the first tank **50** is such that its level does not increase, a message is displayed with instruction to change the source tank**18**. If the first tank **50** is full but the second tank **52** is not, a diverter styled valve (v1), a first valve **56** is held in its normally open (NO) position allowing the first pump **54** to be switched on for filling the second tank 52 through the normally open second diverter valve (v2) **58**. If the fluid level in the second tank **52** still does not increase, a message is again displayed to change source tank **18**.

[0028] The controller **16** verifies at a later time (time #1) that the supply hose **24** at location (h1) is attached to a receptacle/connector **60** by checking the status of micro switch (ms1) **62**. The micro switch **62** must be closed to begin user keypad interface operation. The controller **16** will switch valve (v3) **64** allow flow to the first tank **50** and the first valve **56** and the first pump (p1) **54** and second pump (p2) **66** to wet the system flow lines **68** to be ready for connection to the target tank **20**.

[0029] After a predetermined wetting time, the first valve (v1) **56** is turned off and pressure is delivered to the system lines **68** until it is measured at approximately 30 PSI, by way of example, and indicated by a signal from a pressure transducer (pt1) **70**. The controller **16** will then turn off the first valve **56** and the first (p1) and second (p2) pumps **54, 66**.

[0030] The controller **16** will then display a message to disconnect the hose **28** at the connector (mm2) **60** and connect the hose connector **22** to the target tank connector (mm3) **26**.

[0031] Once the hose **28** is connected at (mm3) to the target tank **20**, the controller will sense a pressure drop at the transducer (pt1) **70** indicating that the system line **68** has been connected. The transfer and filling process can then start.

[0032] The controller **16** then takes the preset conditions (GPM and pre-programmed total), initiating the fill cycle.

[0033] During this fill cycle, the material/product (e.g. Dibrom) is first transferred from the first tank **50** (t1) to the target tank **20**. If more product is needed to complete the fill cycle, flow from the second tank **52** (t2) will be switched by the controller **16** using the third switching valve **64** (v3) to the second tank (t2) and refilling the first tank (t1) by second switching valve **58** (v2) to the first tank **50** (t1) and also turning on the first pump **54** (p1). The controller **16** will check the weight of the first tank **50** using a signal from the load cell **33** until a full condition indication has been met. The controller will then turn the first pump **54** (p1) off, while metering the output of the second tank **52** (t2) using its associated load cell **33**, or alternatively by using a flow metering device. If more material is required to complete the filling of the target tank **20**, this step is repeated with a toggling between the first and second tanks.

[0034] The controller **16** will transfer a pre-programmed quantity of product (Dibrom) to the target tank **20**. If the target tank **20** becomes full before the pre-programmed amount, pressure in the target tank will be sensed by a pressure sensing switch (pss1) **72** operable within vent/vapor line **74** of the system **10** for providing a pressure signal to the controller **16** via control input lines **76** lines operable with the controller indicating that the second pump **66** must be turned off and a two-way valve (v4) **78** closed. By way of example, when filling is within 2 gallons of the pre-programmed amount, the controller **16** will taper (slow) the rate of the second pump (p2) **66** output until a desired amount is reached. During the transfer and filling operation, vapor from the target tank **20** is transferred back to the source tank **18** via the line **74** to keep the system **10** closed to the surrounding/outside environment.

[0035] Should an emergency condition exist, pressing the large emergency stop button **30** will immediately close the two-way valve (v4) **78** and all operating system components. To restart the system, the emergency stop

button **30** must be manually reset as will be indicated by a message from the controller **16**.

[0036] Operation includes draining the hose **28**. Upon completion of the filling of the target tank **20**, the controller **16** will display a message "do you want to fill another tank". If your keypad entry is a "no," the controller **16** will display a message to disconnect the connectors **22/26** (mm3) from the target tank **20**, retract the hose **28** on its hose reel **80** and connect the hose connector **26** to the connector/receptacle **60** (mm2). If your answer and keypad entry id a "yes," the controller **16** will display message to disconnect connectors **22/26** (mm3) from the target tank **20**, retract the hose **28** on the reel **80** to prevent damage to the hose and connector **26**, and do not reconnect to the receptacle **60** (mm2). This will leave the system lines **68** wet for filling additional target tanks.

[0037] When connecting to (mm2) **60** after filling has been completed, the controller **16** will sense a signal from a micro switch (ms1) **82** indicating a closure and thus indicating that the hose **28** is connected. The controller **16** will then open a fifth valve (v5) **84** (a three-way valve) to provide air into the fluid system lines **68** to prevent hose collapse during drainage. In addition to opening the fifth valve **84**(v5), the controller **16** will open the first valve (v1) **56**, close the two-way valve (v4) **78** and turn on the first pump (p1) **54**. The controller will then make a determination as to which tank, the first(t1) or the second (t2) is to be used for draining the hose **28** and will position the second valve (v2) **58** accordingly for draining the hose based on which tank is less full. This operation will continue until no further material/product is pumped into one of these two tanks as sensed by the corresponding load cells **33**.

[0038] The last step in this sequence to be performed is to fill both the first (t1) and second (t2) tanks **50**, **52**. After this final sequence is complete, the computer TDS2020 will go into "sleep mode" after a predetermined time period.

[0039] By way of further example and use of alternate embodiments of the present invention, consider an operation of the second subsystem **14** with

reference again to FIG. 3 for a use of the invention in mixing and transferring chemical materials within a closed system **11**. In the example herein described, liquid inputs to the system **11** are an insecticide chemical carried within the source tank **18** and a dilution chemical, either oil or water (if dilution is required) carried within the dilution tank **86**. As earlier described with reference to FIG. 1, dry connectors **22**, **26** are used on the source tank **18** with the mosquito chemical.

[0040] As earlier described with reference to FIGS. 1 and 2, the chemical materials transfer flow process is automatic and controlled by the controller **16** (after the necessary start data has been entered at the keypad **38**). Process feedback is achieved by reading data from the various system sensors and process hardware control is via on/off switches at 5 volts and 24 volts or PWM signals (24 volt) to system pumps. The accuracy of the materials mixing is dependent upon the accuracy of the load cells **33** used. It is expected to be within better than 2%.

[0041] The transfer of chemical material from the source tank **18** to the target tank **20** including mixing of the chemical material with a diluent transferred form the dilution tank **86** will assume that a particular mixing of the insecticide and dilution chemical is required. One preferred embodiment of the present invention includes the following sequential process steps for this insecticide chemical transfer from the source tank **18** to the target tank **20**, some of which steps may be eliminated depending upon the requirements imposed by the chemicals being transferred and the desires of the user.

[0042] As way similarly described for the operation of system **10**, with reference to FIG. 2, the controller **18** verifies at an initial time (time #0) that the tank (t1) **50c** and the tank (t2) **52c** levels are full. If tank (t1) **50c** is not full, pump (p1) **54c** is switched on. If tank (t1) **50c** levels still do not increase, a message is displayed to change the source tank **18**. If tank (t1) **50c** is full but tank (t2) **52c** is not, valve (v1) **58c** and pump (p1) **54c** are both switched on until a full condition is indicated. If tank (t2) **52c** levels still do not increase, a message is again displayed to change the source tank **18**.

[0043] If mixing with a dilution chemical is not required, the controller **16** will not attempt to fill tank (t3) **50d** and tank (t4) **52d**. If mixing is required, the controller **16** will also verify at time (time #0) that tank (t3) **50d** and tank (t4) **52d** levels are full. If tank (t3) **50d** is not full, pump (p3) **54d** is switched on. If tank (t3) **50d** levels still do not increase, a message is displayed to change the dilution tank **86**. If tank (t3) **50d** is full but tank (t4) **52d** is not, valve (v4) **58d** and pump (p3) **54d** are both switched on until the controller **16** receives a sensing signal indicating a full condition. If tank (t4) **52d** levels do not rise at any time during this sequence, a message is displayed to change the dilution tank **86**.

[0044] The controller 16 verifies at time (time#1) that the hose (h1) **28** is attached to the receptacle (mm2) **60**, as earlier described with reference to FIG. 2, by checking the status of micro switch (ms1) **62**, which micro switch (ms1) must be closed to begin user keypad interface operation. The controller **16** will switch on valve (v2) **64c** and valve (v5) **64d** as well as pumps (p2) **66c** and (p4) **66d** at preferably low flow rates, and switch a transfer pump (p5) **88** on and off until a fifth tank (t5) **90** within this mixing system **11** is full. A tank level sensor (tsf) **92** signals the controller **16** that the tank (t5) **90** is full. The controller **16** will then turn off pump (p5) **88** and close a valve (v9) **94** located between the tank **90** and the pump **88** connected to the receptacle/connector **60**. The controller will then turn off pump (p2) **66c** & pump (p4) **66d** when a pressure transducer (pt1) operable within the system line indicates 30 PSI. This sequence indicates that the system 11 is within a wet condition.

[0045] The controller **16** will then display a message to disconnect the hose (h1) **28** at the connector (mm2) **60** and connect the hose connector 26 to the target tank connector (mm3) **22**.

[0046] Once the hose **28** has been connected using the connectors (mm3) **22/26** to the target tank **20**, the controller **16** will receive a signal from the pressure sensor indicating a pressure drop at (pt1) indicating that the system **11** is closed, properly connected, and ready to start the filling process.

[0047] The controller **16** will now take the preset conditions and programmed requirements (GPM, mix ratio, pre-programmed total, and the like) and will initiate the transfer and filling cycle.

[0048] In the way of providing further example with regard to using the system 11 without mixing, such as is known for RTU products, the controller 16 will first open valve (v6) **98**, close valve (v5) **64d** and turn on pump (p4) **66d** until a tank level empty signal from level sensor (tse) **100** is indicated in tank (t5) **90**. In this embodiment, once the +5 volt signal has been sensed from the (tse) sensor **100**, the controller **16** will close valve (v6) **98**, and turn off pump (p4) **66d**. During this fill cycle, product is transferred from tank (t1) **50c** first to the target tank **20**. The controller **16** will turn on pump (p2) **66c** and open valve (v2) **64c**. If additional product is needed to complete the filling cycle, and tank (t1) **50c** is empty, tank (t2) **52c** will be used by the controller **16** switching valve (v2) **64c** to tank (t2) **52c** and valve (v1) **58c** and pump (p1) **54c** to refill tank (t1) **50c**. The controller **16** will check the weight of tank (t1) **50c** until a full indication has been met, then turn pump (p1) **54c** off, while metering the output of tank (t2) **52c**. If yet additional product is required to complete the filling of the target tank **20**, this step is repeated, toggling between the two tanks **50c**, **52c**.

[0049] Consider the mixing of the chemical material with diluent, keeping in mind that while a liquid is used herein by way of example for the mosquito control industry, it is anticipated that any fluid, including beads by way of example, may be used in the transfer now having the benefit of the teachings of the present invention. This step including a mixing is as previously described except that both are accomplished simultaneously. It is to be noted that when a three-way manually operated valve, valve (v3) **102** is used to select between oil or water dilutions, the controller **16** will display a message to check the manual position of this valve accordingly. This sequence will be the same as that described for the RTU but with different components designated to complete the task, as will herein be described. The controller **16** must first open valve (v6) **98**, close valve (v5) **64d** and turn on pump (p4) **66d**

until a tank level empty (tse) is indicated for tank (t5) **90**. Once the +5 volt signal has been sensed from the (tse) sensor **100**, valve (v6) **98** is closed and valve (v5) **64d** is opened. During this cycle, product is first transferred from tank (t3) **50d** to the target tank **20**. The controller **16** will turn on pump (p4) **66d** and open valve (v5) **64d**. If additional product is needed to complete the transfer and fill cycle and tank (t3) **50d** is empty, the controller 16 will switch operation to tank (t4) **52d** by switching valve (v5) **64d** to tank (t4) **52d**, valve (v4) **58d** to tank (t3) **50d**, and pump (p3) **54d** to be used to refill tank (t3). Using a signal from the appropriate load cell 33, the controller **16** will check the weight of tank (t3) **50d** until a full indication has been met, then turn pump (p3) **54d** off, while metering the output of tank (t4) **52d**. If yet additional product is required to complete the filling of the target tank **20**, this step is repeated, toggling between the two tanks **50d**, **52d**. It should be herein that the use of a pair of tanks **50**, **52** described with reference to FIG. 2, and tank pairs **50c**, **52c** and **50d**, **52d** may each be replaced by single larger capacity tank. However, the use of tank pairs minimizes the need for the large volume subsystems **12**, **14** by toggling between the tanks within the tank pairs. Further, it should be appreciated based on the teachings of the present invention, that the tank pairs in combination with the associated load cells combine to provide a measure of flow and flow rate. Alternatively, flow meters may be used.

[0050] In the mixing cycle of the embodiment of the system **11** herein described by way of example, the controller **16** controls the mixing ratio of pump (p2) **66c** and pump (P4) **66d** with the output going through a mechanical mixer (m1) **104** through additional valves and hose **28**, which hose is conveniently carried on a reel **80**, as earlier described with reference to FIG. 2, and out to the target tank **20**.

[0051] Again, if an emergency condition exists, pressing the large red emergency stop button **30** illustrated with reference again to FIGS. 1 and 4, will immediately close valve (v7) **106** positioned intermediate to the mixer 104 and target tank 20, as illustrated in FIG. 3. In addition, the system operation

will be turned off. In order to restart the system, the emergency stop button **30** must be manually reset as is indicated by an automatically displayed message from the controller **16**.

[0052] The system 11, as performed by the controller **16**, will transfer a predetermined and pre-programmed quantity of product to the target tank **20**. If the target tank **20** becomes full before the pre-programmed amount has been reached, pressure in target tank **20** will be sensed by a pressure sensing switch (pss1) **108** communicating with the controller **16** indicating that pumps (p2 and p4) **66c**, **66d** need to be turned off, valve (v7) **106** is to be closed. Preferably, when filling within approximately 2 gallons of the pre-programmed amount, the controller **16** will taper (slow down) the flow rates and thus outputs of pumps (p2 and p4) **66c**, **66d** until the desired amount is reached.

[0053] During the filling operation, vapor from the target tank **20** is transferred back to the source tank **18** to keep the system **11** closed to the surrounding environment. Venting the vapor back to the source tank **18** is accomplished by monitoring pressure in the source tank using the pressure sensing switch (pss2) **110** until reaching approximately 3 to 5 PSI, which will supply a +5 volt signal to the controller **16**, resulting in the controller in turn closing solenoid valve (v10) **112** to divert vapor through a carbon filter **114**, and out to the surrounding environment if appropriate for the chemical materials being transferred.

[0054] Once the transfer operation is completed, it is desirable to drain the hose **28**. Upon completion of the filling of the target tank **20**, the controller **16** will display a message such as "do you want to fill another tank". If the answer is "no," the controller will display a message to disconnect the connectors (mm3) **22**, **26** from the target tank **20**, retract the hose **28** onto the reel **80** and connect the hose connector **26** to the receptacle/connector (mm2) **60**. If the answer is "yes," the controller **16** will display a message to disconnect (mm3) **22**, **26** from the target tank **20**, retract the hose **28** onto the reel **80** to prevent damage to hose and connector, and do not reconnect to (mm2) **60**. This will leave the lines of the system **11** wet for filling additional tanks.

16

[0055] With continued reference to FIGS. 3A, 3B, and 3C, when connecting to receptacle/connector (mm2) **60** after filling has completed, the controller **16** receives a sensed signal from the micro switch (ms1) **62** indicating a closure and that the hose (h1) **28** is connected to the system **11**. The controller **16** will then open a three-way valve (v8) **116** located inline between the two-way valve (v7) **106** and the exit portion of the hose **28**, close valve (v7) **106** and turn on pump (p5) **88**. This sequence will continue until the tank empty sensor (tse) **100** indicates a condition other than empty, plus a predetermined time, but not a full indication signaled by the sensor (tsf) **92**.

[0056] The last sequence to be performed will be to fill tanks (t1 & t2) **50c**, **52c**, and (t3 & t4) **50d, 52d** if applicable. After this final sequence is complete, the processor **17** (TDS2020) as earlier described with reference to FIGS. 1 and 4, will place the system into a "sleep mode" after a predetermined time period.

[0057] Although the invention has been described relative to specific embodiments thereof, there are numerous variations and modifications that will be readily apparent to those skilled in the art in light of the above teachings. It is therefore to be understood that, within the scope of the appended claims, the invention may be practiced other than as specifically described.
